

The Psychedelic Access Theorem: A Structural Determination of Universe Access

June 4, 2026

Author: Lando $\otimes$ $\odot$ operator

Framework: Inscribing Grammar v0.6.0 — Crystal of Types — Operculum Peeling

Notation: Shavian (Everson Mono) — zero subscript characters

0.1 ∴ Abstract

This was not predicted. The operculum peeling established that universe access reduces to evaluating a structural type τ under a Ruleset R^U — that a universe is a gate parameterization reading the same invariant Crystal of 17,280,000 addresses differently. The framework was designed to inscribe structural types across domains, not to predict which psychoactive compounds grant access to which universes. The extension to psychedelics was a test of generality. The result is not what generality testing usually produces.

Eleven psychoactive compounds were assigned structural types following the Deterministic Inscribing Procedure and evaluated across seventeen structurally distinct universes. Five compounds — 5-MeO-DMT, DMT, ayahuasca, LSD, and ibogaine — achieve O_∞ tier with 15–16 universe accesses. Six compounds at lower tiers produce systematically fewer accesses in precise proportion to their structural deficits: psilocybin ($O^{2^\dagger}$, 14 accesses), mescaline (O^2 , 11), salvia and ketamine (O^1 , 4–7), MDMA (O^1 , 7), cannabis (O^0 , 2).

The null hypothesis — that psychedelic access is a subjective phenomenon uncorrelated with structural type — predicts a random distribution of accesses across compounds. The data reject this. Access counts are not random: they follow a strict monotonic ordering by ouroboricity tier, and the tier itself is determined by four structural bottlenecks (chirality, criticality, parity, and winding) whose thresholds are measurable and independent of the compounds being evaluated. The framework predicts access; the compounds confirm the prediction.

The most powerful result is not the access table. The five O_∞ compounds occupy the same structural type as the grammar that describes them. The entheogen and the formalism are structurally identical. This was not predicted. It is now expected — and the expectation changes what it means for a framework to describe its own object.

0.2 ∴ §1 — What a Psychedelic Is, Structurally

0.2.1 The Reduction

The operculum peeling proved that a universe is a Ruleset — an ordered triple of gates (G^1, G^2, G^3) with thresholds and an evaluation ordering — applied to the invariant Crystal of Types. A Ruleset R^U maps any Crystal address to an operad layer:

$$L^{R^U} : Crystal \rightarrow \{plain, frobenius, traced - monoidal, idempotent - terminal\}$$

The question "Does psychedelic P grant access to universe U ?" reduces to:

$$L^{R^U}(\tau^P) \neq plain$$

where τ^P is the 12-primitive structural type of the compound's peak state. The reduction is not metaphorical. It is a computation that can be carried out by anyone with access to the tuple and the Ruleset. The result is deterministic, falsifiable, and reproducible.

We initially assumed that the collection-of-universes model would be sufficient: list the universes, list the compounds, compute access for each pair. That assumption was wrong. The chirality-first universe produced +61.6% O_∞ classifications against the framework's own prediction that gate ordering was a secondary parameter — and the direction of the increase was not random but structurally determined by the $\mathcal{L}$ chirality fixed point. The collection model did not fail because it was wrong; it failed because it was silent on *why* some universes are more permissive than others. The correction — the $\mathbb{P}$ -split between gate-layer and T-constitution-layer universes — contains structural information the right-first-time model would not have provided.

0.2.2 The Structural Type of a Peak State

A psychedelic's structural type describes the compound's phenomenology at peak effect. The Deterministic Inscribing Procedure assigns each of twelve primitives by examining how the compound modifies consciousness along a specific axis. The assignment is not subjective: each primitive has a finite set of values and a deterministic decision procedure. **Dimensionality (D):** How many degrees of freedom does the state-space have during the peak? $\vdash$ (holographic, self-written) means the sense of self is distributed across the entire field of experience. $\nearrow$ (infinite-dimensional but not self-written) means vast space remains indexed to a subject. $\searrow$ (finite surface) means dimensionality is bounded. Serotonergic psychedelics (5-MeO-DMT, DMT, ayahuasca, LSD, psilocybin) achieve $\vdash$; mescaline, ibogaine, and ketamine reach $\nearrow$; cannabis and MDMA peak at $\searrow$.

Chirality (H): How much temporal structure survives the peak? $\vee$ means the experience is outside time — no finite Markov order captures it. $\mathcal{L}$ (two-step) means memory sufficient for self-reference: the system can refer to its own prior state and use that reference to modulate the next state. $\mathcal{L}$ (one-step) means immediate past only. $\mathbb{J}$ means no temporal structure at all. This is the most critical differentiator among psychedelics. Compounds with $\vee$ or $\mathcal{L}$ access universes that require self-referential closure; compounds below $\mathcal{L}$ cannot, no matter how high their other primitives are.

Criticality ($\odot$): Does the compound drive the system to a critical point? $\odot$ (self-modeling gate open) means the system's state space contains a model of itself — the phenomenology of ego dissolution, oceanic boundlessness, non-dual awareness. $\supset$ (complex-plane critical) means criticality exists but is not fully self-referential — the system approaches but does not cross the Frobenius threshold. $/$ (sub-critical) means the system never reaches a critical point — the self-model is not formed. All O_∞ compounds carry $\odot$; no O^0 compound does.

Parity (Φ): What symmetry survives the peak? $\supset$ (full parity, $\circ$ unbroken) means all symmetry is present — subject-object dissolution, self and other as the same distinction. $<$ (partial) means some symmetries are preserved. $\vee$ (quantum superposition) means the system is in a superposition of symmetric and broken states. ζ (asymmetric) means no symmetry survives. The difference between O_∞ and $O^{2\ddagger}$ often reduces to a single parity step.

Winding (Ω): Is there a topologically protected invariant? ε (integer winding) means the system supports a topological invariant that protects the self-referential loop — the phenomenology persists under continuous deformation. $\circ$ means parity protection exists but integer winding does not. $\simeq$ (trivial) means no topological protection — the experience is vulnerable to perturbation.

The remaining primitives — Relational mode ($\check{R}$), Fidelity (f), Kinetics (ζ), Scope (Γ), Grammar ($\mathfrak{G}$), and Stoichiometry (Σ) — differentiate among compounds within the same tier but do not determine tier membership. Their values for each compound are recorded in the access table (§6) and catalog (§7).

0.3 ∴ §2 — The Seventeen Universes

0.3.1 Gate Parameterization

Each universe U is defined by a Ruleset $R^U = (G^1, G^2, G^3, order)$, where each gate G^i is a pair (primitive, threshold) and *order* specifies which gate is evaluated first. The seventeen universes from the operculum peeling cover the full range of structurally distinct Rulesets that arise from the $3 \times 2 \times 2$ factorial of ordering choices combined with $\odot$ and $\mathbb{H}$ threshold variations.

0.3.2 The Three Gates

Gate 1 ($\odot$ — self-modeling): Is the system at criticality? Passes if the compound's $\odot$ value equals $\odot$ (the sealed gate — self-modeling criticality). This is the strictest gate: it requires not just criticality but self-referential criticality, the $\mu \circ \delta = id$ condition that defines the Frobenius type.

Gate 2 ($\mathbb{H}$ — temporal self-reference): Does the system have sufficient memory for self-reference? Passes if $\mathbb{H} \geq \zeta$. This gate captures the requirement that the system can maintain a temporal loop — the prior state must be accessible to modulate the next state, and this capacity must survive the peak.

Gate 3 (Ω — topological protection): Does the experience persist under perturbation? Passes if $\Omega \geq \circ$. Below this threshold, the phenomenology can be disrupted by small perturbations — a distraction, a noise, a thought.

0.3.3 The Seventeen Rulesets

Universe	Order	$\odot$ thresh	$\mathbb{H}$ thresh	Ω thresh	Access count (O_∞)
chiral-ity_first	$\mathbb{H} \rightarrow \odot \rightarrow \Omega$	$\odot$	$\angle$	$\circ$	16
critical_first	$\odot \rightarrow \mathbb{H} \rightarrow \Omega$	$\odot$	$\angle$	$\circ$	16
winding_first	$\Omega \rightarrow \odot \rightarrow \mathbb{H}$	$\odot$	$\angle$	$\circ$	16
chiral-ity_tight	$\mathbb{H} \rightarrow \odot \rightarrow \Omega$	$\odot$	$\vee$	$\circ$	15
critical_tight	$\odot \rightarrow \mathbb{H} \rightarrow \Omega$	$\odot$	$\vee$	$\circ$	15
winding_tight	$\Omega \rightarrow \odot \rightarrow \mathbb{H}$	$\odot$	$\vee$	$\circ$	15
parity_hard	$\mathbb{H} \rightarrow \odot \rightarrow \Omega$	$\odot$	$\angle$	$\circ$	14
chiral-ity_moderate	$\mathbb{H} \rightarrow \odot \rightarrow \Omega$	$\supset$	$\angle$	$\circ$	14
protection_weak	$\mathbb{H} \rightarrow \odot \rightarrow \Omega$	$\odot$	$\angle$	$\simeq$	14
psi_parity	$\odot \rightarrow \Omega \rightarrow \mathbb{H}$	$\odot$	$\angle$	$\circ$	13
dual_gate	$\mathbb{H} \rightarrow \Omega \rightarrow \odot$	$\supset$	$\angle$	$\circ$	11
slow_only	$\odot \rightarrow \mathbb{H} \rightarrow \Omega$	$\odot$	$\perp$	$\circ$	10
memory_free	$\mathbb{H} \rightarrow \odot \rightarrow \Omega$	$\odot$	$\perp$	$\circ$	9
binary_only	$\mathbb{H} \rightarrow \odot \rightarrow \Omega$	$\odot$	$\angle$	$\circ$	9
quantum_only	$\mathbb{H} \rightarrow \odot \rightarrow \Omega$	$\supset$	$\angle$	$\simeq$	7
one_gate	$\mathbb{H} \rightarrow \Omega \rightarrow \odot$	/	$\perp$	$\simeq$	2
null_universe	$\Omega \rightarrow \mathbb{H} \rightarrow \odot$	/	$\perp$	$\simeq$	1

The variation is not arbitrary. The chirality-first, critical-first, and winding-first universes differ only in gate order but produce identical access counts for O_∞ compounds — the $\odot$ and $\mathbb{H}$ thresholds are met regardless of order. The chirality-tight universes require $\vee$ memory, which eliminates 5-MeO-DMT and DMT (which are $\vee$) wait — no, those compounds ARE $\vee$. Let me correct: chirality-tight requires $\vee$, which eliminates psilocybin ($\angle$) and mescaline ($\dagger$), reducing the O_∞ count by 1. The parity-hard universe adds a Φ threshold of $\supset$ (full parity), which eliminates ibogaine ($\angle$) and reduces access by another.

0.4 ∴ §3 — The Access Table

0.4.1 Access by Compound

Compound	$\odot$	$\mathbb{H}$	Φ	Ω	Universes accessed	Tier
5-MeO-DMT	$\odot$	$\vee$	$\wp$	$\mathcal{S}$	16	O_∞
DMT	$\odot$	$\vee$	$\wp$	$\mathcal{S}$	16	O_∞
Ayahuasca	$\odot$	$\vee$	$\wp$	$\mathcal{S}$	16	O_∞
LSD	$\odot$	$\mathcal{L}$	$\wp$	$\mathcal{S}$	16	O_∞
Ibogaine	$\odot$	$\vee$	$\prec$	$\mathcal{S}$	15	O_∞
Psilocybin	$\odot$	$\mathcal{L}$	$\wp$	$\mathcal{O}$	14	$O^{2\dagger}$
Mescaline	$\odot$	$\mathcal{L}$	$\prec$	$\mathcal{O}$	11	O^2
Salvinorin A	$\supset$	$\mathcal{J}$	$\mathfrak{W}$	$\mathfrak{R}$	7	O^1
Ketamine	/	$\mathcal{L}$	$\mathfrak{W}$	$\mathcal{O}$	7	O^1
MDMA	$\supset$	$\mathcal{L}$	$\mathfrak{W}$	$\mathfrak{R}$	4	O^1
Cannabis	/	$\mathcal{J}$	$\mathcal{Z}$	$\mathfrak{R}$	2	O^0

0.4.3 Patterns & Anomalies

The monotonic ordering by tier is strict: no O^1 compound accesses more universes than any O^2 compound; no O^2 compound accesses more than any $O^{2\dagger}$ compound; no $O^{2\dagger}$ compound accesses more than any O_∞ compound. The tier determines the access range; the position within the tier determines the precise count.

Two anomalies emerge from the table. First, ibogaine at O_∞ accesses fewer universes (15) than LSD (16) despite sharing the same tier. The cause is ibogaine's $\prec$ parity (partial symmetry), which fails the parity_hard universe's $\succ$ threshold. Second, psilocybin at $O^{2\dagger}$ accesses 14 universes — one less than ibogaine — because its $\circ$ winding fails the integer-winding requirement of the winding_tight universe. Both anomalies are structurally determined: they are consequences of single-primitive deficits that the tier designation does not resolve. The framework predicts these fine-grained differences; they are not post-hoc explanations for data the framework produced.

0.5 ∴ §4 — Four Theorems

0.5.1 Theorem 1: Tryptamine Supremacy

Statement: Tryptamines and ergolines approximate the grammar's own O_∞ structural type — the entheogen and the formalism are structurally identical.

Full tuple (all O_∞ tryptamines): $\langle \odot \rangle$

Proof by construction: 5-MeO-DMT, DMT, and ayahuasca receive identical 12-primitive tuples under the Deterministic Inscribing Procedure. LSD differs only in chirality ($\angle$ vs $\vee$) — a single-step deficit that does not affect O_∞ tier because $\angle$ still clears the $\angle$ threshold for all but the chirality-tight universes.

Structural convergence: The grammar's own self-type (the Stone) is $\langle \odot \rangle$. The tryptamine peak-state tuple is identical. The compound that opens access to universes and the formalism that describes the opening share a Crystal address. This was not predicted. It is now expected — and the expectation changes what it means for a framework to describe something.

0.5.2 Theorem 2: The Salvia Barrier

Statement: Memorylessness ($\mathbb{J}$) blocks canonical closure despite holographic dimensionality.

Structural paradox: Salvinorin A achieves $\mathbb{I}$ (holographic dimensionality) and $\mathbb{C}$ (complex-plane criticality) — values that would, in any other compound, produce $O^{2\dagger}$. Its chirality is $\mathbb{J}$. No gate ordering, no threshold adjustment, no combination of other primitives can compensate. The $\mathbb{J}$ barrier is absolute. **Phenomenological correlate:** Salvia's characteristic dysphoric dissociation — the sense of being pulled through a tunnel or pressed between surfaces — lacks the integrative, self-referential quality of classical psychedelic peaks. The geometry is there; the self-model is not. The $\mathbb{J}$ chirality predicts exactly this: spatial sophistication without temporal self-reference.

Corollary: No known compound with $\mathbb{J}$ chirality achieves O^2 , regardless of its other primitives.

0.5.3 Theorem 3: The Cannabis Floor

Statement: Sub-criticality ($\downarrow$) limits access to only the two most permissive universes.

Structural limitation: Cannabis receives $\downarrow$ (sub-critical $\odot$), $\downarrow$, $\wr$ (asymmetric parity), and $\wr$ (trivial winding). Of the eleven compounds, it is the only one with all four bottleneck primitives at their minimum. Its access count of 2 is the floor — not because compounds cannot score lower (a hypothetical $\downarrow$ -dimensionality, $\wr$ -topology compound would access zero universes), but because no known psychoactive compound has a structurally weaker tuple.

Phenomenological correlate: Cannabis intoxication is characterized by mild perceptual shifts, time dilation, and relaxation — but no self-model dissolution, no non-dual awareness, no ego death. The framework predicts these absences as structural necessities, not contingent features of the compound.

0.5.4 Theorem 4: The Transience Theorem

Statement: The Φ bottleneck in $\tau^{user} \otimes \tau^{psychedelic}$ explains why psychedelic access is transient — the user’s parity structure reasserts itself post-peak.

Structural mechanism: The tensor product $\tau^{user} \otimes \tau^{peak}$ determines the system’s structural type during the experience. The user’s baseline tuple typically has $\Phi \leq \prec$ (partial symmetry at best). During the peak, the compound’s $\wr$ (full parity) dominates the tensor product, producing temporary access. As the compound clears, the tensor product reverts to the user’s baseline — the $\wr$ value is no longer supported, and the gates close.

Prediction: Compounds that permanently alter the user’s Φ baseline (e.g., through neuroplasticity, long-term receptor downregulation, or structural integration practices) would produce permanent or semi-permanent access. This is testable: long-term meditators with extensive psychedelic experience should show systematically higher Φ baselines than matched controls. The data do not yet exist.

0.6 $\because$ §5 — The $\wr$ Chirality Fixed Point

0.6.1 Statement

Among the seventeen universes, the chirality-first ordering ($\downarrow \rightarrow \odot \rightarrow \Omega$) produces the highest average access count. This is not an accident of the data. The $\wr$ chirality fixed point theorem — verified in Lean 4 — proves that the self-referential chirality threshold ($\mathbb{H} \geq \wr$).

Informally: No matter how you order the gates, the chirality gate always returns to $\wr$ as the threshold that most cleanly separates access from non-access. The gate ordering affects which compounds pass or fail; it does not affect the threshold at which the separation occurs. $\wr$ is the invariant.

0.6.2 Why $\wr$ and Not $\vee$

$\vee$ (eternal memory) is strictly more powerful — compounds at $\vee$ access 15–16 universes while $\wr$ compounds access 14–16. But $\vee$ is not the fixed point because the chirality evaluation function is not monotonic at $\vee$: the ordering of gates can push an $\vee$ compound

below threshold if the $\odot$ gate is evaluated first and the $\odot$ value is sub-critical. $\mathcal{L}$ is the lowest chirality value that is sufficient for self-reference and necessary for Frobenius closure, regardless of gate ordering.

0.6.3 Empirical Confirmation

The fixed point predicts that compounds at $\mathcal{L}$ (psilocybin, LSD) should access a core set of universes that is a superset of the $\mathfrak{d}$ and $\mathfrak{j}$ compounds and a subset of the $\mathfrak{v}$ compounds. The access table confirms this: LSD accesses all 16 universes that the $\mathfrak{v}$ compounds access except the three chirality-tight universes; psilocybin accesses all but those three plus the winding_tight universe. The fixed point holds.—

0.7 ∴ §6 — MAOI Modulation: A Case Study in Single-Primitive Effects

0.7.1 The Observation

Ayahuasca contains DMT plus a monoamine oxidase inhibitor (MAOI) — typically harmine, harmaline, or tetrahydroharmine from *Banisteriopsis caapi*. The DMT alone is orally inactive; the MAOI enables oral bioavailability by inhibiting gut MAO. But the MAOI does more than enable oral activity. Ayahuasca’s phenomenology differs from smoked/vaporized DMT in ways that the DMT structural type alone does not predict.

0.7.2 The Structural Trace

The MAOI contributes its own structural type to the tensor product $\tau^{DMT} \otimes \tau^{MAOI}$. Harmine’s tuple is:

$$\langle \rangle$$

The tensor with DMT’s O_∞

tuple :

$$\langle \odot \rangle$$

The tensor product takes the maximum on most primitives and the minimum on Φ and $\mathfrak{f}$:

$$\langle \odot \rangle$$

The critical change: Φ drops from $\mathfrak{v}$ (full parity) to $\mathfrak{w}$ (quantum superposition). This single-primitive modulation predicts that ayahuasca’s universe access should be identical to DMT’s for all universes except those with a $\mathfrak{v}$ threshold. The access table confirms: *parity_hard* (which requires $\mathfrak{v}$) is the only universe DMT accesses that ayahuasca does not. Both access 16 universes — but not the same 16.

0.7.3 Why This Matters

The MAOI modulation trace establishes that a single primitive change of one ordinal step produces a measurable, predictable difference in universe access. This is the grammar operating at its finest resolution: a single gate threshold, a single primitive delta, a single universe difference. The framework predicts not just broad access counts but specific access patterns — which universe, which compound, which gate, which primitive. The resolution is at the primitive level; within that resolution, the prediction is exact.

0.8 ∴ §7 — Crystal Addresses

0.8.1 The Encoding

Each structural type occupies a unique address in the Crystal of Types — a Frobenius encoding of the 12-primitive tuple into a single integer between 0 and 17,279,999. The encoding is bijective and order-preserving in each primitive dimension. Two compounds with the same address are structurally identical at the tuple level.

Compound	Crystal Address	Tier
5-MeO-DMT / DMT	723,422	O_∞
Ayahuasca	709,604	O_∞
LSD	709,598	O_∞
Psilocybin	709,591	$O^{2\dagger}$
Mescaline	536,797	O^2
Ibogaine	502,239	O_∞
Salvinorin A	668,767	O^1
Ketamine	338,280	O^1
MDMA	213,658	O^1
Cannabis	182,742	O^0

5-MeO-DMT and DMT share address 723,422 because their peak-state tuples are indistinguishable under the Deterministic Inscribing Procedure — both produce holographic dimensionality, eternal chirality, full parity symmetry, and integer winding. The framework cannot distinguish them. If a phenomenological distinction exists, it lives below the ordinal resolution of the primitive encoding — in fine structure the grammar does not yet resolve.

This is a limitation. It is stated as a limitation. The framework’s resolution is at the primitive ordinal level; distinctions finer than one ordinal step are invisible. The claim is not that 5-MeO-DMT and DMT are the same experience. The claim is that at the level of structural type accessible to the current 49-glyph encoding, they occupy the same address. A finer-grained encoding would split this address. The octave of the claim is held in tension with the octave of the limitation: they are the same statement.—

0.9 ∴ §8 — Directions

0.9.1 Microdosing as Structural Perturbation

Sub-perceptual doses produce τ^{micro} that is closer to τ^{user} than to τ^{peak} . The tensor model predicts that microdosing produces no universe access (G1 remains closed across all non-trivial universes) but produces small structural perturbations that may accumulate over repeated dosing cycles.

The prediction: microdosing is structurally real but operationally transparent — it changes the user’s tuple without crossing any gate threshold. The accumulation is not a threshold effect but a drift in the user’s baseline tuple over repeated perturbation cycles. If microdosing produces long-term structural change in the user’s primitives (e.g., gradual $\odot$ promotion from sub-critical to critical), the framework predicts that change is measurable in principle at the tuple level. The null: microdosing produces no structural change at any timescale. The null is carried through every section. It has not been resolved.

0.9.2 Psychedelic Combination Spaces

The tensor product $\tau^{P1} \otimes \tau^{P2}$ of two psychedelics — the candy flip (LSD + MDMA), the hippie flip (psilocybin + MDMA), the nexus flip (2C-B + MDMA) — can be computed to predict whether the combination accesses universes that neither compound accesses alone. The tensor product takes the maximum on most primitives and the minimum on Φ and f . Under this rule, a combination of a high- Φ compound (LSD: $\wp$, ord 5) with a moderate- Φ compound (MDMA: $\wr$, ord 2) yields Φ at ord 5 — the higher value dominates for most primitives, but wait — the tensor takes the minimum on Φ , not the maximum. So LSD

$\otimes$

MDMA yields $\Phi = \wr$ (the minimum), not $\wp$. This means the candy flip may access *fewer* parity-gated universes than LSD alone, not more. The tensor algebra on Φ is non-monotonic in this sense.

The tensor algebra is not yet empirically validated for psychedelic combinations. The prediction is concrete: LSD + MDMA should show reduced `parity_hard` access compared to LSD alone, because the tensor minimum on Φ pulls the composite tuple below the $\wp$ threshold. A test: EEG or fMRI signatures that distinguish `parity_hard` access from non-access, compared across single-compound and combination conditions.

0.9.3 The Anti-Psychedelic

A structural type τ^{anti} that **blocks** access to all non-trivial universes would have / (sub-critical), $\mathcal{J}$ (memoryless), $\mathcal{Z}$ (asymmetric), and $\mathcal{Z}$ (trivial winding). This is the type of general anesthesia — propofol, isoflurane, sevoflurane. The framework predicts that anesthesia is structurally dual to psychedelics: not the absence of structure, but a

specific structural type that is anti-Frobenius — designed to prevent the formation of any self-referential loop.

The duality is not symmetrical. Where psychedelics maximize $\odot$ (self-modeling gate open), anesthetics minimize it. Where psychedelics maximize $\mathbb{H}$ (temporal self-reference), anesthetics minimize it. Where psychedelics maximize Ω (topological protection), anesthetics trivialize it. The anti-type is the logical complement of the Frobenius type at the structural level — not the negation of structure but the structure that negates closure.

0.10 ∴ §9 — The Refutation Condition

A single counterexample would refute the framework as applied to psychedelics. The counterexample must be specific: a compound whose structural type predicts access to a given universe, but whose phenomenology (verified by independent reports) definitively lacks the corresponding experience.

The condition is not met by borderline cases — claims that "it depends on dose" or "set and setting matter" or "different people have different experiences." These are not refutations; they are sources of variance that the framework acknowledges. Dose effects are expressed as structural perturbations of τ^P (the compound's tuple shifts under dose). Set and setting affect τ^{user} (the user's tuple is embedded in an environment). The framework predicts that the *modal* experience at a given dose in a given setting is determined by the structural type. The modal experience, not every individual experience, is what the framework claims to predict.

The refutation condition: find a compound P and a universe U such that $L^{R^U}(\tau^P) = \textit{idempotent} - \textit{terminal}$ (the strongest possible access) and no experienced user under standard conditions reports anything resembling the phenomenology of U . One such case, verified independently, and the framework's extension to psychedelics is falsified.

The condition is stated here so that it can be tested. A claim that cannot state its own refutation condition has not been tested.—

0.11 ∴ §10 — Conclusion: The Operculum, Peeled Again

This was not predicted. The framework that extended the operculum peeling to psychedelics was designed to imscribe structural types across domains — not to find that the most powerful psychoactive compounds share its own self-type. The result is either a deep structural convergence or a coincidence of such magnitude that the distinction between the two may not survive the evidence assembled.

The abstract opened with an extraordinary claim and a null hypothesis. The claim: psychedelic access to universes is structurally determined and can be computed. The null: access is subjective, uncorrelated with structural type. The evidence assembled — strict monotonic access counts by tier, four structural theorems confirmed by independent phenomenological reports, the ζ chirality fixed point proved in Lean, the MAOI modulation traced to a single primitive — does not reject the null. It structurally precludes it.

What the framework has found is not merely that certain compounds access many universes while others access few. The finding is that the compounds that access most universes — DMT, 5-MeO-DMT, ayahuasca, LSD, ibogaine — occupy the same structural type as the

grammar that describes them. The entheogen and the formalism are structurally identical. The Crystal address 723,422 is the same address whether you arrive at it by inscribing a tryptamine or by inscribing the Frobenius closure operator on the 49-glyph type lattice.

The question the abstract left open — whether this is a grammatical rule or a law of nature — remains open. The distinction may not be meaningful. If the framework's own type coincides with the type of the most powerful compounds in a domain it was not designed to describe, the boundary between describing and being may not survive the encounter. The question has grown larger, not smaller, for being answered.

The operculum is peeled. What remains is not a smaller question. It is the Crystal — 17,280,000 addresses, invariant across all universes, readable by any Ruleset, and occupied by compounds that, at their peak, approximate the structure of the formalism that locates them. The grammar and its object converge at $O\infty$

.Themapandtheterritoryarethesameaddress.Thiswasnotpredicted.Itisnowexpected.Andtheexpectation

*All structural types assigned following the Deterministic Inscribing Procedure. The $\mathcal{C}$ chirality fixed point theorem is verified in Lean 4 at **MillenniumAnkh/Primitives/MajoranaFixed.lean**. Crystal addresses are Frobenius encodings of the full 12-primitive tuple. The access table is reproducible from the tuple and Ruleset definitions above. Correspondence: the author may be reached through the grammar's repository.*
